
Royalty Reporting Automation

System Overview and Handover Document

Document	System overview for the client
Version	1.0
Date	1 September 2026
Prepared by	Alian Software
Audience	Business owner and operations team

This document explains what the system does, when it runs, how it is built, what it stores, and what happens when something goes wrong. It is written to be read without any technical background.

Contents

About this document

Everything described here is what the system does today, not what it is planned to do. Where something is not finished, or is held up waiting on another party, it is named as such in section 12 rather than left out.

A note on wording

Technical names have been replaced with plain descriptions throughout. Where a term is unavoidable it is explained the first time it appears.

1 What this system does

It keeps a complete, reliable copy of your WellnessLiving business data in a database you own, so that royalty reporting can be produced from it.

WellnessLiving holds your bookings, clients, staff, purchases and payments, but it will not produce the royalty figures you need, and its reports cannot be extended. Reading the numbers out by hand each month is slow and easy to get wrong.

This system reads that information automatically, every night, and stores it in a database that belongs to you. Once the data is in one place and in a consistent shape, a royalty report becomes a query rather than a month of manual work.

What it does, in order of importance

Collects	Reads clients, staff, purchases, payments, classes and attendance from WellnessLiving, and marketing contacts from GoHighLevel.
Never changes your source data	Both connections are read-only. The system cannot alter, delete or create anything in WellnessLiving or GoHighLevel.
Stores it once	Running the same sync twice updates the existing records rather than creating a second copy of them. Duplicates are prevented by design, not by cleanup afterwards.
Keeps the evidence	The original response from each service is stored alongside the tidy version, so a question about any figure can be answered from what was actually received.
Recovers on its own	A slow response or a brief outage is retried automatically. The run continues around whatever failed rather than stopping.
Tells you when it cannot	If something genuinely needs a person, an email is sent explaining what and why. Nothing else generates email.

The principle behind the design

A silent failure is worse than a loud one. Every part of this system is built so that a problem shows up as a problem, rather than as a report that looks complete and quietly is not.

2 How information moves

There are two sources, one service that does the work, and one database that holds the result. Nothing else has access to your data.

Figure 1 — The path data takes, from source to stored record.

Reading each part

The sources	WellnessLiving is the system of record for your business. GoHighLevel adds marketing contact detail. The system only ever reads from them.
The sync service	Runs on a schedule with no server to maintain. It wakes up, does its work, and stops. You are not paying for it to sit idle.
The database	A PostgreSQL database hosted on Supabase. It is yours: the data can be queried, exported or moved elsewhere at any time.
The outputs	Royalty reporting reads from this database. A student portal is planned to read from the same place, so both always agree.
The email alert	Sent only when the system has given up on something. Described fully in section 10.

3 The two schedules

The system runs on its own, on two separate schedules. Neither needs anybody to start it.

4 How current the data is

The database is refreshed every night. Knowing the schedule tells you exactly how current any figure is at the moment you look at it.

Worked examples

What happens in WellnessLiving	When it appears in your database
A client buys a ten-class pass on Tuesday evening	Wednesday morning, after the 03:00 run
A class runs on Tuesday, and attendance is finalised on Wednesday	Thursday morning — and the run keeps re-reading the previous seven days, so a late change is picked up rather than missed
A refund is processed on Friday afternoon	Saturday morning, with the refund shown against the original purchase
A member books a class three weeks ahead	The same night — the schedule is read thirty days into the future

The rule of thumb

Anything that happens today is in the database by tomorrow morning. The longest the database can be behind is one night.

If you need it sooner than tomorrow

A sync can be triggered on demand at any time of day and takes effect immediately — useful before producing a report, or when something has just been corrected in WellnessLiving. Running it more often is harmless: records that have not changed are simply confirmed.

Why there is a monthly run as well

The nightly run keeps the present accurate. The monthly run is the safeguard for the recent past: on the 1st of each month it automatically re-reads **the last two months** of classes and appointments in full, whether or not anyone has asked it to.

Why it is needed	The nightly run looks back a few days, which is right for catching an attendance figure that was finalised late. It is not enough for a class edited three weeks after it ran. The monthly re-read catches exactly that.
Every month, once	Because it works in whole calendar months, each month is re-read once, in full, shortly after it ends. No period is skipped, and re-reading corrects a record rather than duplicating it.
Loading older history	If you want last year's class history included in reporting, that range is requested once and loaded one calendar month at a time. A request like this takes priority over the routine two-month re-read.

5 What the daily sync covers

Nine areas are refreshed each night, in a fixed order. The order matters: each step depends on the one before it.

#	Area	What is read, and why it comes here
1	Reference lists	Membership types, locations, shop categories, promotions and service categories. Everything else points at these, so they are refreshed first.
2	People	Clients and staff. A purchase cannot be stored before the person who made it exists.
3	Purchases	What was bought, by whom, and when. These become the rows a royalty is calculated from.
4	The money	Totals, payments, account credit and refunds for each purchase. Read separately because WellnessLiving does not include amounts in the purchase list.
5	Purchase detail	Membership state, renewal and hold dates, and who each purchase was actually for — which is not always the person who paid.
6	Contact details	Email, phone and date of birth for each person. This is the only place a client's primary email address appears.
7	Classes and appointments	The class schedule and private appointments, across the rolling window.
8	Attendance	Who attended each class that ran, and what the outcome was.
9	Match and catalogue	Matching each person to their GoHighLevel contact, then refreshing the bookable service catalogue. Both run last because they depend on everything above.

If a run does not finish

The nightly run stops starting new work shortly before its time limit and reports how far it got. Nothing is lost: the outstanding work stays on the list and the next run continues from exactly there.

6 How the backend is put together

The system is built in four layers. Each layer only speaks to the one below it, which is what allows any single part to be changed or replaced without disturbing the rest.

Figure 3 — The four layers, and what sits in each.

1 · Ways in	Four entry points: the two automatic schedules, a read-only status check, and a manual run for when somebody needs to trigger a sync deliberately. All four are protected by an access token; without one, they refuse to answer.
2 · The sync engine	The decision-making layer. It keeps the list of every record still to be fetched, watches the clock so a run ends by choice rather than being cut off, applies the retry rules, and records what each run achieved.
3 · Talking to others	All outside communication happens here and nowhere else. This is what makes the read-only guarantee checkable rather than a promise.
4 · Storage and support	Saving to the database, the settings, the password store, and the activity log. Passwords are stripped from the log before it is written.

7 What the database holds

The tables fall into seven groups. The first four are your business record. The last three exist so the system can be checked and corrected.

Figure 4 — The seven groups of tables.

Alongside the tables there are ready-made views — saved questions that can be asked at any time without writing anything new. They answer things like which services are unrecognised, which clients have not been matched to a marketing contact, and how far the current sync has got.

8 The rules the database follows

A few decisions shape everything else. They were each made for a measured reason, and they are the reason the data can be trusted for money reporting.

One human is one row

A person who is both a client and a teacher is a single record, not two. "Clients" and "teachers" are two different ways of looking at the same list. This prevents the most common and most damaging kind of error in this sort of system: the same person counted twice.

The purchased item is the royalty row

A single purchase can contain several items, and a royalty is owed on the item, not on the transaction. Storing the item as the row means a royalty figure never has to be reverse-engineered out of a total.

Money is stored exactly

Every amount is held to exactly two decimal places, never as an approximate number. Approximate numbers drift by fractions of a penny as they are added up, and in a royalty figure that drift cannot be traced back or corrected afterwards.

Nothing is ever stored twice

Every record is saved against the identifier WellnessLiving gave it. Re-running a sync updates what is there. This is why a sync can be safely re-run at any time, and why an interrupted run is never a problem.

The original response is kept

Every answer received is stored exactly as it arrived, next to the tidy version. If a field turns out to have been interpreted wrongly, it can be corrected from the stored copy — without going back to WellnessLiving and without losing the history.

Disagreements are flagged, never guessed

Where two sources say different things about the same record — or where a marketing contact could plausibly match two different people — the system records the disagreement for a person to settle. It does not pick one. Putting one client's royalties onto another client's record is not an error that gets noticed later.

9 What happens when something fails

Failures are expected, not exceptional. An internet service is occasionally slow, briefly unavailable, or asks to be called less often. The system is built around that.

Figure 5 — The path a single record takes when it fails.

One failure is not a failed run	Each record is handled independently. If one fails, the rest of the run carries on.
Three retries, spaced apart	Waiting one minute, then five, then twenty-five. Most problems are gone by the second attempt.
Then it is set aside	Rather than retrying for ever, the record is put aside and reported. A permanent problem is not solved by trying again more often.
Success is verified, not assumed	WellnessLiving sometimes reports a failure inside an otherwise normal-looking response. Every answer is checked for what it actually says before it is used. This is the single most important check in the system.

10 The alert email

One email address is notified when the system gives up on something. The rule for sending is deliberately strict.

You are emailed about	You are never emailed about
Records the system has stopped retrying	A slow response that succeeded on retry
A stage that stopped before finishing	A request to slow down
Nothing else	A run that did part of its work and will continue tonight

The same problem is not emailed twice for the same run, and a healthy run sends nothing at all. An email arriving means something has changed.

What the email looks like

Subject: Royalty sync: 3 record(s) could not be updated

The most recent royalty sync finished, but 3 record(s) across 2 area(s) could not be updated after several attempts.

Here is what happened, grouped by what needs the same next step:

- 2 record(s) in purchase receipts (the money side).
Reason: WellnessLiving reported the record does not exist. It may have been deleted after it was first seen. No further retry will help.
Example record(s): 2145, 2199
- 1 record(s) in client profiles.
Reason: WellnessLiving was slow to respond and the request timed out after several retries. Running the sync again later should catch these up.
Example record(s): 9f0021

You do not need to do anything with this email if the numbers are small and the reasons say a later run will catch them up.

What to do when one arrives

Read the reason. If it says a later run will catch it up, no action is needed — check that the next email does not repeat it. If the same message arrives several days running, or the reason mentions authentication, forward it to your technical contact.

11 Keeping your data safe

Read-only by design	The system has no ability to write to WellnessLiving or GoHighLevel. This is not a setting that could be changed by accident — the capability does not exist in the code, and an automated check fails the build if it is ever added.
No passwords in the code	Every password, key and address is supplied to the system when it starts, from a protected store. None of them appears anywhere in the code, and an automated check enforces this on every change.
Passwords stripped from logs	The activity log is cleaned of credentials before it is written, not after. A password cannot reach a log file even if an error message contains one.
Every entry point locked	All four ways into the system require an access token. If no token is configured, the entry point refuses everyone — it never falls back to being open.
Separate environments	Test and live run against entirely separate credentials and separate databases. Nothing carries over between them.
Rotation is documented	Each password has a written procedure for replacing it, including how to confirm the new one works before the old one is switched off.

Who can see the data

The database enforces its own access rules. The sync service holds a key that bypasses them — that key is used only by the sync and never reaches a browser, an app, or any other party. A future student portal will use a normal, restricted connection, so a student can only ever see their own record.

12 What is live today, and what is waiting

Stated plainly, because a plan that hides its gaps is not a plan.

Working now LIVE

Reading staff, clients, purchases and the money on each purchase — proven against real data
Membership detail, renewal dates, refunds and who each purchase was for
Contact details for each person, including the primary email address
Class schedule, private appointments and attendance
Reference lists: locations, promotions, shop and service categories, the service catalogue
GoHighLevel contact matching, with unclear matches flagged rather than guessed
The full failure, retry and email alert path

Waiting on WellnessLiving BLOCKED

The full client list	WellnessLiving offers no way to list all clients — its search requires a term to search for. People are currently discovered through staff records, purchases and attendance, which reaches everyone who has transacted but not the wider client base. Needed: confirmation from WellnessLiving of a client list or export endpoint.
Staff pay amounts	WellnessLiving returns which pay rate applies but never the amount, and none of its documented endpoints resolves it. Revenue per class is therefore available; profit per class is not. Needed: either an endpoint we have not found, or the rates supplied to us another way.

Next, once the above is resolved PLANNED

Royalty calculation	The data the calculation needs is now being collected. The calculation itself is the next piece of work.
Student portal	Reading from this same database, so the portal and the reporting can never disagree.

13 Everyday questions

Do I need to do anything to keep it running?

No. Both schedules run automatically. The only thing that needs a person is an alert email, and only when the reason given says so.

What if WellnessLiving is down overnight?

The run retries, then leaves the outstanding work on the list. The next night's run picks it up. No data is lost, and nothing needs restarting by hand.

Can a sync be run in the middle of the day?

Yes. A sync can be triggered manually at any time, and running it more often causes no harm — records that have not changed are simply confirmed.

Will running it twice duplicate anything?

No. Every record is stored against the identifier WellnessLiving gave it, so a second run updates the first result rather than adding to it.

How far back does the data go?

As far back as has been loaded. The nightly run covers the recent window and the monthly run re-reads the last two months; anything older than that is loaded on request, one calendar month at a time.

Is my WellnessLiving data at any risk?

No. The connection is read-only and cannot be made otherwise without changing the code, which an automated check would reject.

Where does the data actually live?

In a PostgreSQL database on Supabase, under your account. It can be queried, exported or moved at any time, and it is not locked to this system.

Who should be contacted about a problem?

Forward the alert email to your technical contact at Alian Software. The email already contains everything needed to begin — which area failed, how many records, and why.
